

When a ledger fails, its performance stays hidden.

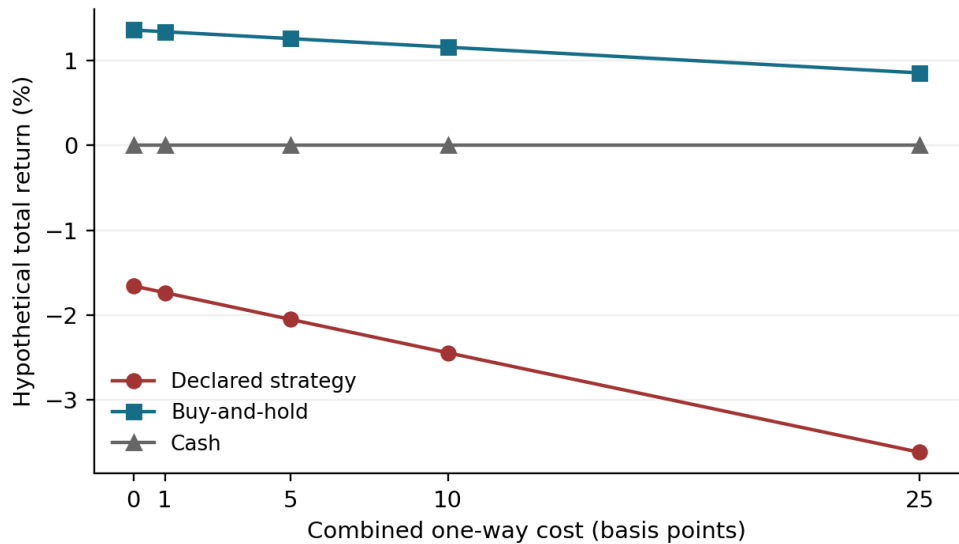

Point-in-time controls for a frozen single-asset evaluation. All results below are software controls on manually specified synthetic values.

58 controls	55 invalid inputs	15 cost comparisons
All matched expectation	All withheld every path	Decimal error <= 3.44e-16

1. Check information before arithmetic

Each decision binds the latest feature and training-label availability. Inputs require timezone-aware times, strictly ordered decisions and contiguous future return intervals. A one-second future-information violation fails at every tested row.

2. Keep a pass separate from a gain

At 10 bps combined one-way cost, the valid strategy returns -2.446481%; buy-and-hold +1.158764%; cash 0%. These are hypothetical fixture calculations, not financial performance.

3. Preserve the review boundary

Hashes identify consumed bytes. They do not authenticate release times. The tool does not certify data licensing, simulate execution or finance, measure production adoption, or reopen a closed forecasting study.

Talk sequence: contract (2 min) -> failed future-feature twin (2 min) -> fixed fault corpus and Decimal check (3 min) -> operational use and limits (3 min). Full source, reports and manuscript accompany this handout. Nothing has been submitted or accepted.
